3 Installation

3.1 Installing the unit

The PGK duct cooler is designed for using chilled water as the cooling medium. The duct cooler coil consists of copper tubes and aluminium fins.

Warning

The cooling coil must not be used for direct-expansion refrigerant.

For air flow, water flow and other technical particulars, see tables in chapter 4.

The cooler should not be installed close to a fan outlet or a duct bend, since the air flow across the coil would then be uneven and the cooling capacity would thus be impaired.

Make sure that the cooler is installed so that the finned coil, drip tray and condensate outlet are accessible for cleaning (chapter 5). The duct cooler should be installed in a horizontal duct, but the air flow may be in either direction. Secure the duct cooler to the duct system by means of screws or slip joints.

The condensate outlet (pos C) in figure 2 should be connected across a water trap in order to avoid air leakage.

Note:

The size of the outlet should be such that no water will remain in the drip tray. When the drip tray is to be removed, ensure that the condensate outlet is easy to disconnect.

An efficient filter is recommended in the system in order to reduce fouling and thus also cut down the need for maintenance (see chapter 5).

The duct cooler should be installed downstream of the fan unit, although it can also be installed upstream, but care should then be taken to ensure that the fan motor and other components will not be harmed by the humid air downstream of the cooler.

The duct cooler must be insulated on the outside, so that no condensate will form. The ducts that carry the chilled air must normally also be insulated.

3.2 Water connections

Operating data: Max. operating temperature/operating pressure 100°C/1.0 MPa (10 bar)

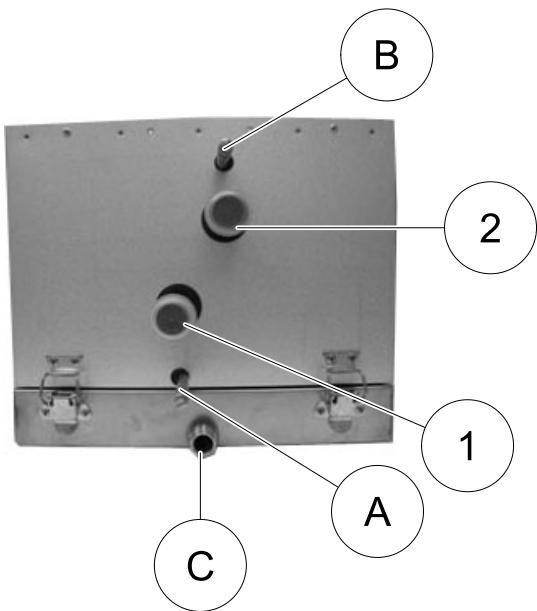

Fig. 2 Water connections

The following must be taken into account when connecting the duct cooler to the pipe system.

1. The pipes connected to the cooler must not be subjected to twisting or bending loads. Use tools to restrain the pipes when tightening the coupling nuts.
2. Ensure that expansion forces in the system or the deadweight of the pipe system are not applied to the connections on the cooler.
3. The water inlet must be connected to the lower pipe (pos 1) and the outlet to the upper pipe (pos 2) in figure 2. The inlet is provided with a drain connection (pos A) and the outlet with an air purging connection (pos B).
4. After the system has been filled with water, check the duct cooler and its connections to ensure that there is no water leakage. Any leakage could cause water damage.
5. The cooling coil can be drained of water through the drain connection (pos A).

Warning

If the water in the coil should freeze, the coil may burst which would allow water to run out of the system, and this could cause water damage. When the duct cooler is not in service and there is risk of freezing, the cooler should be drained of water through the drain connection and blown with compressed air to ensure that all water has been drained.

3.3 Droplet eliminator

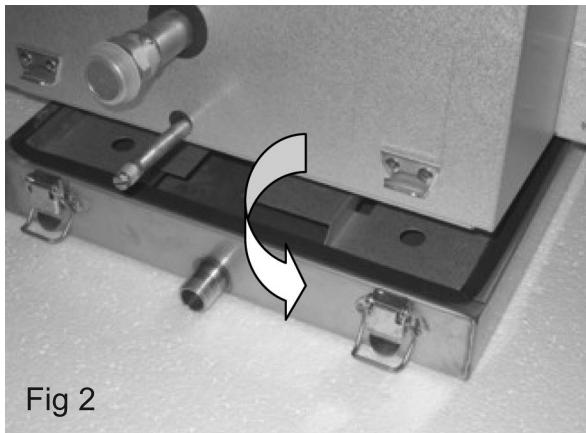

Fig 2

Fig 3

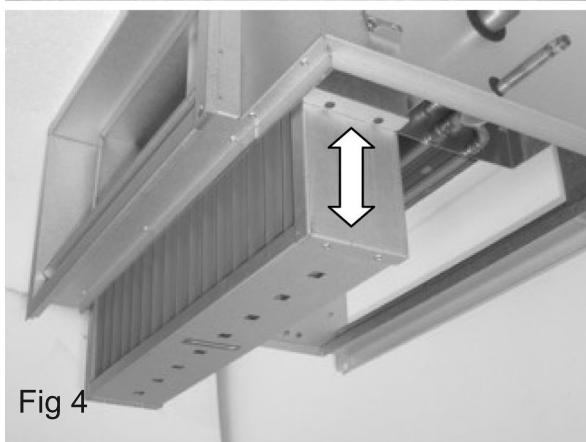

Fig 4

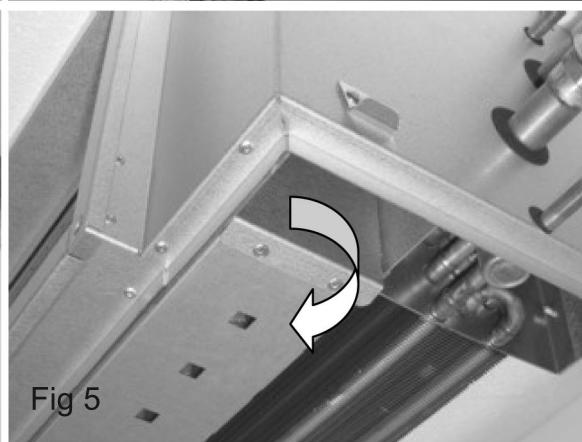

Fig 5

Droplet eliminator DE must be installed downstream of the cooling coil in the duct cooler, viewed in the direction of air flow.

Remove the drip tray from underneath. Push the droplet eliminator up until the holder secures it in position (Fig 5). Carefully check that the air flow is in the direction of the arrow on the droplet eliminator and that the drain holes face downwards towards the drip tray (Fig 3).

5 Maintenance

5.1 Cleaning

In order to ensure full cooling capacity of the duct cooler, the finned coil and the droplet eliminator, if any, must be regularly cleaned. The intervals between cleaning are entirely dependent on the cleanliness of the air and on how well filters and the system in general are maintained.

Caution

- Make sure that there is no one underneath the drip tray when it is being removed.
- Disconnect the condensate outlet, and blank off the connection so that any remaining condensate will not run out.

Remove the drip tray by releasing the excentric lock on the front. Lower the drip tray about 2-3 cm and then move it towards the back so that the locking mechanism at the back will be released. The drip tray is held captive by hinges the rear, but it can easily be released to enable it to be removed from the cooler. If a droplet eliminator is fitted, push the holders to the side (Fig 3), and remove the droplet eliminator for cleaning with compressed air or warm water.

Then clean the inlet side of the coil with a soft brush and the entire coil can then be cleaned by means of compressed air or by vacuum cleaning. Blow away the dirt in a direction from the outlet side of the air towards the inlet. Take care not to deform the thin fin edges.

Clean the bottom of the drip tray and check with your finger that the condensate outlet is not clogged with dirt. Then fit the droplet eliminator, if any (see chapter 3.3), the drip tray and the anti-condensation insulation.
